

# Single Channel PWM Controller with 2 Integrated Drivers for AMD SVI2 GPU CORE Power Supply

## General Description

The RT3662EB is a single channel PWM controller with 2 integrated drivers, and it is compliant with AMD SVI2 Voltage Regulator Specification to support GPU power (VDDC). The RT3662EB features CCRCOT (Constant Current Ripple Constant On-Time) with G-NAVP (Green-Native AVP), which is Richtek's proprietary topology. G-NAVP makes it an easy setting controller to meet all AMD AVP (Adaptive Voltage Positioning) VDDC requirements. The droop is easily programmed by setting the DC gain of the error amplifier. With proper compensation, the load transient response can achieve optimized AVP performance. The controller also uses the interface to issue VOTF Complete and to send digitally encoded voltage and current values for the VDDC domains. The RT3662EB can operate in diode emulation mode to enhance the light load efficiency. And it provides the current gain adjustment capability by pin setting. The RT3662EB provides power good indication, thermal indication (VRHOT\_L), and it features complete fault protection functions including, over current, over voltage and under voltage.

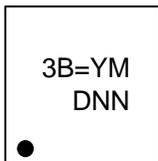

## Features

- 2/1-Phase (VDDC) PWM Controller
- 2 Embedded MOSFET Drivers
- G-NAVP™ Topology
- Support Dynamic Load-Line and Zero Load-Line
- Diode Emulation Mode at Light Load Condition
- SVI2 Interface to Comply with AMD Power Management Protocol
- Adjustable Current Gain Capability
- DVID Enhancement
- 0.5% DAC Accuracy
- Differential Remote Voltage Sensing
- Build-in ADC for Pin Setting Programming, Thermal Indication and VOUT, IOUT Reporting
- Fast Transient Response
- Power Good Indicator
- Thermal Indicator (VRHOT\_L)
- OVP, UVP and UVLO
- Over Current Protection

## Applications

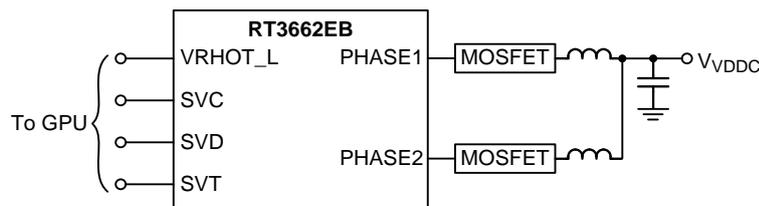

- AMD SVI2 GPU Core Power
- Laptop Computer

## Marking Information

3B= : Product Code  
YMDNN : Date Code

## Simplified Application Circuit

## Ordering Information

RT3662EB □ □

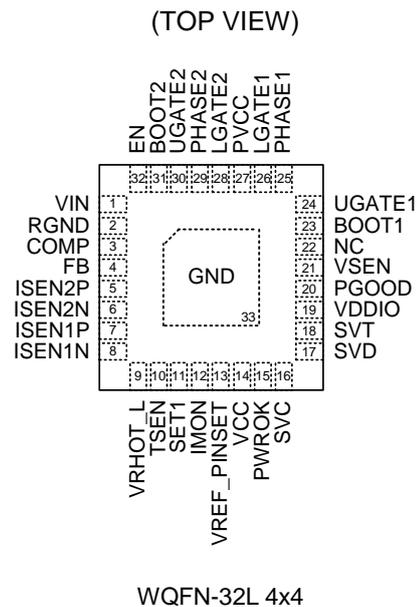

- Package Type  
QW : WQFN-32L 4x4 (W-Type)
- Lead Plating System  
G : Green (Halogen Free and Pb Free)

Note :

Richtek products are :

- ▶ RoHS compliant and compatible with the current requirements of IPC/JEDEC J-STD-020.
- ▶ Suitable for use in SnPb or Pb-free soldering processes.

## Pin Configuration

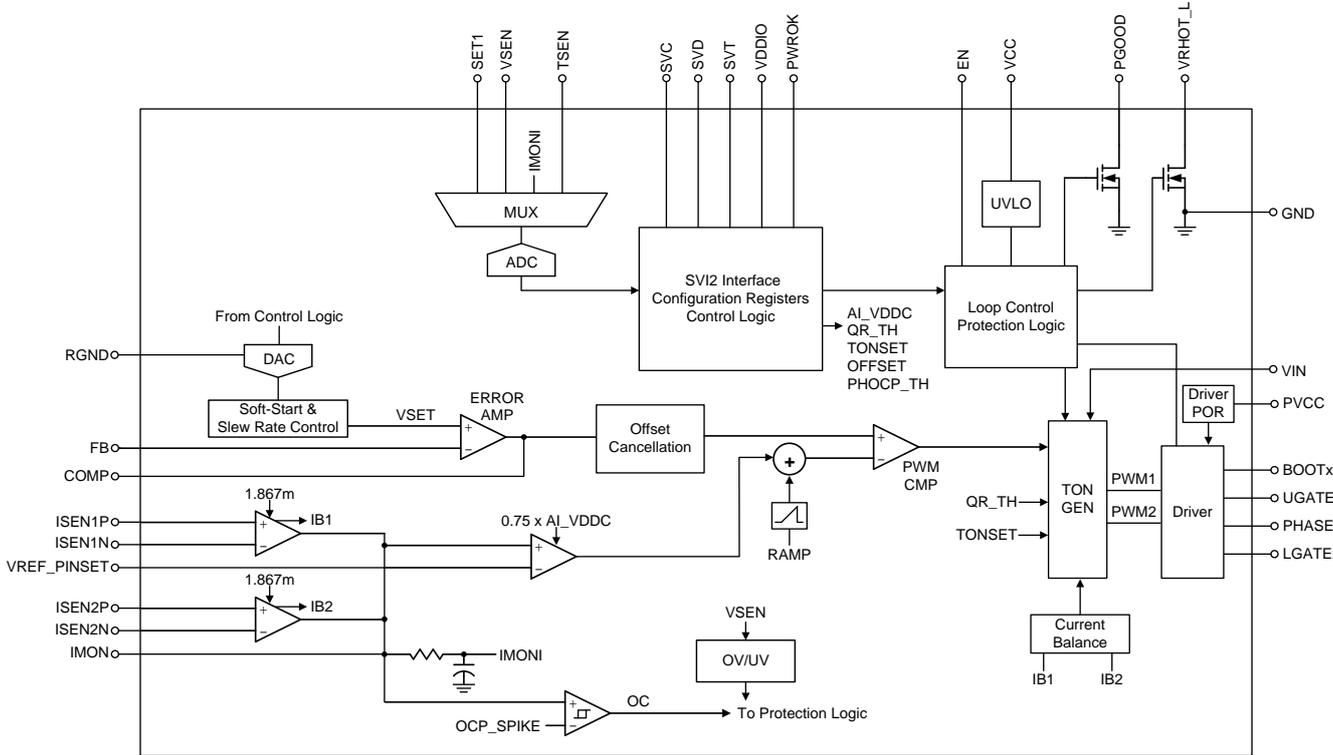

## Functional Pin Description

Pin No.	Pin Name	Pin Function
1	VIN	VIN input. Connect a low pass filter to this pin.
2	RGND	Return ground of VDDC controller. This pin is the common negative input of output voltage differential remote sense of VDDC controller.
3	COMP	Error amplifier output pin of the VDDC controller.
4	FB	Output voltage feedback input of VDDC controller. This pin is the negative input of the error amplifier for the VDDC controller.
5	ISEN2P	Positive current sense input of channel 2 for VDDC controller.
6	ISEN2N	Negative current sense input of channel 2 for VDDC controller.
7	ISEN1P	Positive current sense input of Channel 1 for VDDC controller.
8	ISEN1N	Negative current sense input of channel 1 for VDDC controller.
9	VRHOT_L	Thermal indicator. This pin is an open drain output. (Active low)
10	TSEN	This pin provides two functions: platform setting, platform can use this pin to set frequency, initial offset and per-phase OCP threshold of VDDC Controller. The other function is thermal sense input for VRHOT indicator, so this pin must to be connected to the NTC network for thermal sense.
11	SET1	Platform setting pin. Platform can use this pin to set AI gain, QRTH of VDDC Controller.
12	IMON	Current monitor output for the VDDC controller. This pin outputs a voltage proportional to the output current.
13	VREF_PINSET	This pin provides two functions : the 3.2V power supply for pin setting function divided resistors. The other function is fixed 0.8V output reference voltage, and the voltage is only used to offset the output voltage of IMON pin. Connect a RC circuit from this pin to GND. The recommended resistor is from 3.9 Ω to 10Ω, and the capacitor is 0.47μF.

Pin No.	Pin Name	Pin Function
14	VCC	Controller power supply. Connect this pin to 5V and place a decoupling capacitor 2.2 $\mu$ F at least. The decoupling capacitor is as close controller as possible.
15	PWROK	System power good input. If PWROK is low, the SVI interface is disabled and VR returns to BOOT-VID state with initial load-line slope and initial offset. If PWROK is high, the SVI interface is running and the DAC decodes the received serial VID codes to determine the output voltage.
16	SVC	Serial VID clock input.
17	SVD	Serial VID data input. This pin is a serial data line.
18	SVT	Serial VID telemetry output from VR. This pin is a push-pull output.
19	VDDIO	Processor memory interface power rail and serves as the reference for PWROK, SVD, SVC and SVT. This pin is used by the VR to reference the SVI pins.
20	PGOOD	Power good indicator for the VDDC controller. This pin is an open drain output.
21	VSEN	VDDC controller voltage sense input. This pin is connected to the terminal of VDDC controller output voltage.
22	NC	No internal connection.
23	BOOT1	Bootstrap supply of phase1 for high side MOSFET. This pin powers high side MOSFET driver.
24	UGATE1	Upper gate driver output of phase1. Connect this pin to the gate input of high side MOSFET.
25	PHASE1	Switch nodes of high side driver for phase1. Connect this pin to high side MOSFET Source together with the low side MOSFET Drain and the inductor.
26	LGATE1	Lower gate driver output of phase1. Connect this pin to the gate input of low side MOSFET.
27	PVCC	Driver power supply. Connect this pin to GND by the 2.2 $\mu$ F ceramic capacitor at least. The decoupling capacitor is as close controller as possible.
28	LGATE2	Lower gate driver output of phase2. Connect this pin to the gate input of low side MOSFET.
29	PHASE2	Switch nodes of high side driver for phase2. Connect this pin to high side MOSFET Source together with the low side MOSFET Drain and the inductor.
30	UGATE2	Upper gate driver output of phase2. Connect this pin to the gate input of high side MOSFET.
31	BOOT2	Bootstrap supply of phase2 for high side MOSFET. This pin powers high side MOSFET driver.
32	EN	Controller enable input pin.
33 (Exposed Pad)	GND	Ground. The exposed pad must be soldered to a large PCB and connected to GND for maximum power dissipation.

Functional Block Diagram

Operation

The RT3662EB adopts G-NAVP™ (Green Native AVP) which is Richtek's proprietary topology derived from finite DC gain of EA amplifier with current mode control, making it easy to set the droop to meet all AMD GPU requirements of AVP (Adaptive Voltage Positioning). The G-NAVP™ controller is one type of current mode constant on-time control with DC offset cancellation. The approach can not only improve DC offset problem for increasing system accuracy but also provide fast transient response. When current feedback signal reaches COMP signal, it generates an on-time width to achieve PWM modulation.

MUX and ADC

The MUX supports the inputs from SET1, TSEN, IMONI and VSEN. The ADC converts these analog signals to digital codes for reporting or performance adjustment.

SWI2 Interface/Configuration Registers/Control Logic

The SWI2 interface uses the SVC, SVD, and SVT pins to communicate with GPU. The configuration registers save the digital data from ADC output for reporting or performance adjustment. The Control Logic controls the ADC timing and generates the digital code of the VID for VSEN voltage.

Loop Control Protection Logic

Loop control protection logic detects EN and UVLO signals to initiate the soft-start function, and the PGOOD and VRHOT\_L will be controlled after the soft-start is finished. When VRHOT indication event occurs, the VRHOT\_L pin voltage will be pulled low.

DAC

The DAC receives VID codes from the SWI2 control logic to generate an internal reference voltage (VSET) for controller.

**Soft-Start and Slew-Rate Control**

This block controls the slew rate of the internal reference voltage when output voltage changes.

**Error Amplifier**

Error amplifier generates COMP signal by the difference between VSET and FB.

**Offset Cancellation**

This block cancels the output offset voltage from voltage ripple and current ripple to achieve accurate output voltage.

**UVLO**

Detect the VCC pin voltage for under voltage lockout protection and power on reset operation.

**Current Balance**

Each phase current sense signal is sent to the current balance circuit which adjusts the on-time of each phase to optimize current sharing.

**PWM CMP**

The PWM comparator compares COMP signal and current feedback signal to generate a signal for TONGEN.

**TONGEN**

This block generates an on-time pulse which high interval is based on the on-time setting and current balance.

**RAMP**

The Ramp generator is designed to improve noise immunity and reduce jitter.

**OC/OV/UV**

VSEN and output current are sensed for over current, over voltage and under voltage protection.

- Note 1.** Stresses beyond those listed under “Absolute Maximum Ratings” June cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions June affect device reliability.
- Note 2.**  $\theta_{JA}$  is measured under natural convection (still air) at  $T_A = 25^\circ\text{C}$  with the component mounted on a high effective-thermal-conductivity four-layer test board on a JEDEC 51-7 thermal measurement standard.  $\theta_{JC}$  is measured at the exposed pad of the package.
- Note 3.** Devices are ESD sensitive. Handling precaution is recommended.
- Note 4.** The device is not guaranteed to function outside its operating conditions.
- Note 5.** Min. SVC frequency defined in electrical spec. is related with different application. As min. SVC < 1MHz, VR can't support telemetry reporting function. As min. SVC < 400kHz, VR can't support telemetry reporting function and VOTF complete function.
- Note 6.**  $\text{TON}_{[\text{PSI0\_L:PSI1\_L=00,01,10}]} = 0.8 * \text{TON}_{[\text{PSI0\_L:PSI1\_L=11}]}$

## Application Information

### Power Ready (POR) Detection

During start-up, the RT3662EB will detect the voltage at the voltage input pins : VCC, PVCC and EN. When  $VCC > 4.3V$  and  $PVCC > 3.85V$ , the IC will recognize the power state of system to be ready (POR = high) and wait for enable command at the EN pin. After POR = high and  $V_{EN} > 2V$ , the IC will enter start-up sequence for VDDC. If the voltage of VCC and EN pin drop below low threshold, the IC will enter power down sequence and all the functions will be disabled. Normally, connecting system power to the EN pin is recommended. The SVID will be ready in 2ms (max) after the chip has been enabled. All the protection latches (OVP, OCP, UVP) will be cleared only after POR = low. The condition of  $V_{EN} = \text{low}$  will not clear these latches.

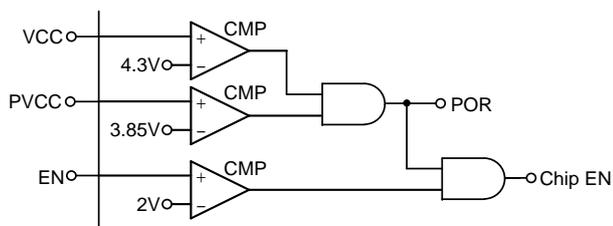

Figure 1. Power Ready (POR) Detection

### Boot VID

When EN goes high, VDDC output begin to soft-start to the Boot VID in CCM. Table 5 shows the Boot VID setting. The Boot VID is determined by the SVC and SVD input states at EN rising edge and it is in the internal register. The digital soft-start circuit ramps up the reference voltage at a controlled slew rate to reduce inrush current during start-up. When all the output voltages are above power good threshold (300mV below Boot VID) at the end of soft-start, the controller asserts power good (PGOOD) after a time delay.

Table 5. 2-Bit Boot VID Code

Initial Startup VID (Boot VID)		
SVC	SVD	VDDC Output Voltage (V)
0	0	1.1
0	1	1.0
1	0	0.9
1	1	0.8

### Start-Up Sequence

After EN goes high, the RT3662EB starts up and operates according to the initial settings. Figure 2 shows the simplified sequence timing diagram. The detailed operation is described in the following.

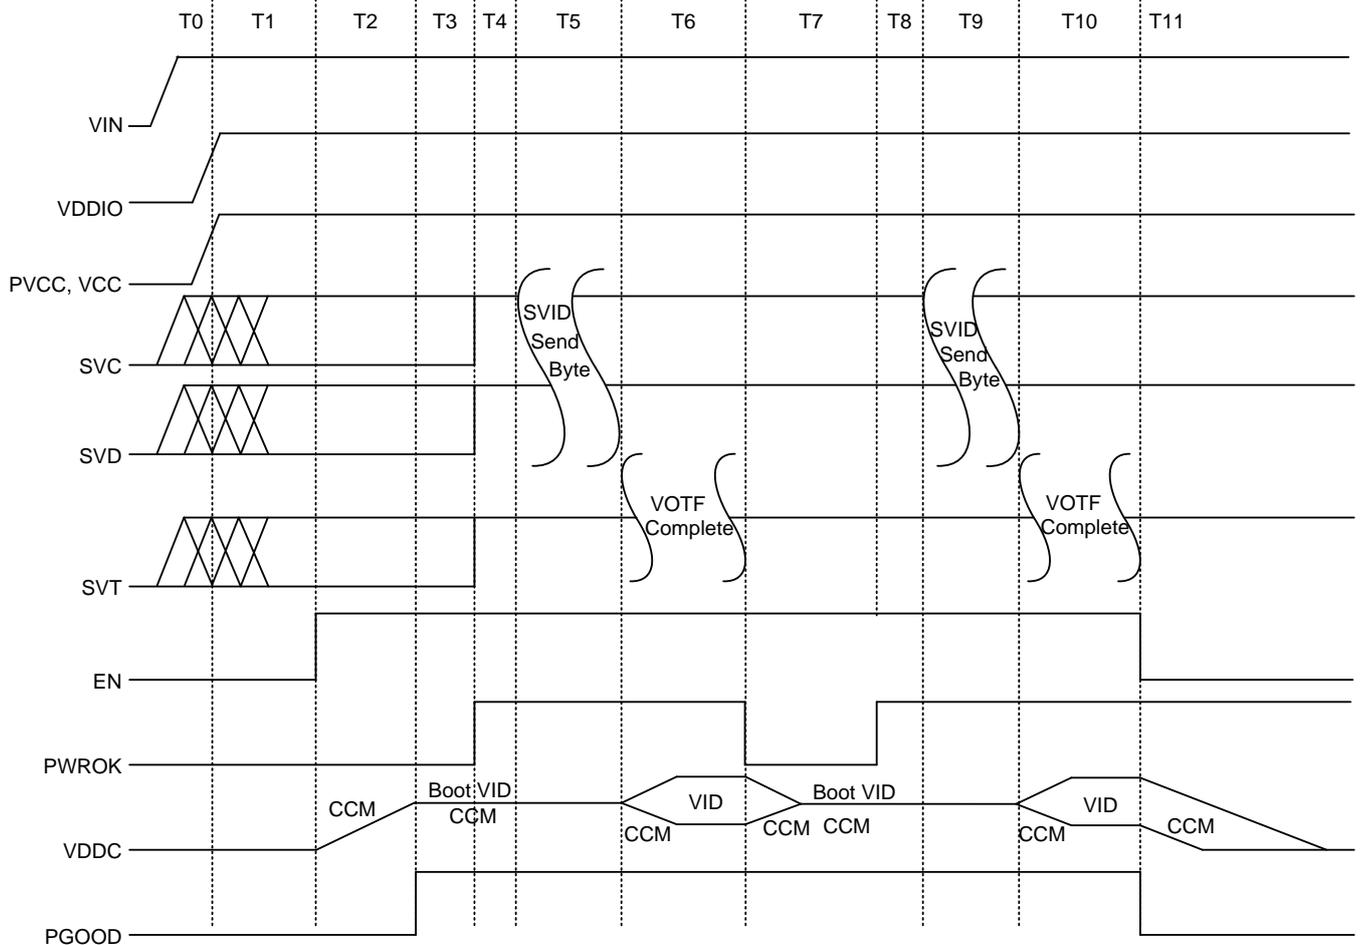

Figure 2. Simplified Sequence Timing Diagram

Description of Figure 2 :

T0 : When the VIN power is ready, the RT3662EB will wait for VCC and PVCC POR.

T1 : VDDIO power is ready, and the BOOT VID can be set by SVC pin and SVD pin, and latched at EN rising edge. SVT is driven high by the RT3662EB.

T2 : The enable signal goes high and all output voltages ramp up to the Boot VID in CCM. The soft-start slew rate is 2.5mV/μs.

T3 : All output voltages are within the regulation limits and the PGOOD signal goes high.

T4 : The PWROK pin goes high and the SVI2 interface starts running. The RT3662EB waits for SVID command from processor.

T5 : A valid SVID command transaction occurs between the processor and the RT3662EB.

T6 : The RT3662EB starts VOTF (VID on-the-Fly) transition according to the received SVID command

and send a VOTF Complete if the VID is greater than BOOT VID and reaches target VID.

T7 : The PWROK pin goes low and the SVI2 interface stops running. All output voltages go back to the Boot VID in CCM.

T8 : The PWROK pin goes high again and the SVI2 interface starts running. The RT3662EB waits for SVID command from processor.

T9 : A valid SVID command transaction occurs between the processor and the RT3662EB.

T10 : The action is same with T6. The RT3662EB starts VID on-the-Fly transition and send a VOTF Complete if the VID up and reaches target VID.

T11 : The enable signal goes low and all output voltages enter soft-shutdown mode. The soft-shutdown slew rate is 2.5mV/μs.

## Power-Down Sequence

If the voltage at the EN pin falls below the enable falling threshold, the controller is disabled. The voltage at the PGOOD pin will immediately go low when EN pin signal goes low, and the VDDC controller executes soft-shutdown operation. The internal digital circuit ramps down the reference voltage at the same slew rate as that of in soft-start, making VDDC output voltage gradually decrease in CCM. The Boot VID information stored in the internal register is cleared at POR. This event forces the RT3662EB to check the SVC and SVD inputs for a new Boot VID when the EN voltage goes high again.

## PGOOD

The PGOOD is open-drain logic output. It provides the power good signal when VDDC output voltage is within the regulation limits and no protection is triggered. The pin is typically tied to 3.3V or 5V power source through a pull-high resistor. During shutdown state (EN = low) and the soft-start period, the PGOOD voltage is pulled low. After a successful soft-start and VDDC output voltage is within the regulation limits, the PGOOD is released high.

The voltage at the PGOOD pin will be pulled low when any of the following events occurs : over-voltage protection, under-voltage protection, over-current protection, and logic low EN voltage.

## SVI2 Wire Protocol

The RT3662EB complies with AMD's Voltage Regulator Specification, which defines the Serial VID Interface 2.0 (SVI2) protocol. With SVI2 protocol, the processor directly controls the reference voltage level of each individual controller channel and determines which controller operates in power saving mode. The SVI2 interface is a three-wire bus that connects a single master to one or above slaves. The master initiates and terminates SVI2 transactions and drives the clock, SVC, and the data, SVD, during a transaction. The slave drives the telemetry, SVT during a transaction. The AMD processor is always the master. The voltage regulator controller (RT3662EB) is always the slave. The RT3662EB receives the SVID code and acts accordingly. The SVI protocol supports 20MHz high speed mode I<sup>2</sup>C, which is based on SVD data packet. Table 6 shows the SVD data packet. A SVD packet consists of a "Start" signal, three data bytes after each byte, and a "Stop" signal. The 8-bit serial VID codes are listed in Table1. After the RT3662EB has received the stop sequence, it decodes the received serial VID code and executes the command. The controller has the ability to sample and report voltage and current for the VDDC domains. The controller reports this telemetry serially over the SVT wire which is clocked by the processor driven SVC. A bit TFN at SVD packet along with the VDDC domain selector bits are used by the processor to change the telemetry functionality. The telemetry bit definition is listed in Figure 3. The detailed SVI2 specification is outlined in the AMD Voltage Regulator and Voltage Regulator Module (VRM) and Serial VID Interface 2.0 (SVI2) Specification.

**Table 6. SVD Data Packet**

Bit Time	Description
1 : 5	Always 11000b
6	VDDC domain selector bit, if set then the following two data bytes contain the VID, the PSI state, and the load-line slope trim and offset trim state for VDDC.
8	Always 0b
10	PSI0_L
11 : 17	VID Code bits [7:1]
19	VID Code bit [0]
20	PSI1_L

Bit Time	Description
21	TFN (Telemetry Functionality)
22 : 24	Load Line Slope Trim [2:0]
25 : 26	Offset Trim [1:0]

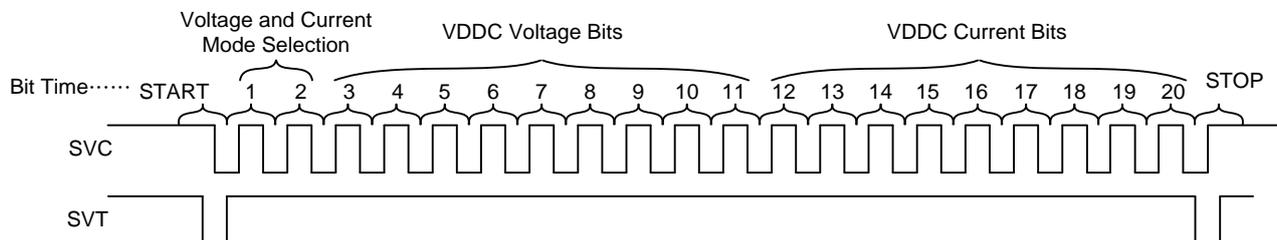

Figure 3. Telemetry Bit Definition

**PWROK and SVI2 Operation**

The PWROK pin is an input pin, which is connected to the global power good signal from the platform. Logic high at this pin enables the SVI2 interface, allowing data transaction between processor and the RT3662EB. Once the RT3662EB receives a valid SVID code, it decodes the information from processor to determine the output target VID. The internal DAC then steps up/down the reference voltage in a controlled slew rate, making the output voltage shift to the required new VID. If the PWROK input goes low during normal operation, the SVI2 protocol stops running. The RT3662EB immediately drives SVT high and modifies all output voltages back to the Boot VID, which is stored in the internal register right after the controller is enabled. The controller does not read SVD and SVC inputs after the loss of PWROK. If the PWROK input goes high again, the SVI2 protocol resumes running. The RT3662EB then waits to decode the SVID command from processor for a new VID and acts as previously described. The SVI2 protocol is only runs when the PWROK input goes high after the voltage at the EN pin goes high.

**VID on-the-Fly Transition**

After the RT3662EB has received a valid SVID code, it executes the VID on-the-Fly transition by stepping up/down the reference voltage of the required controller channel in a controlled slew rate, hence allowing the output voltage to ramp up/down to target VID.

During the VID on-the-Fly transition, the RT3662EB will force CCM operation in high performance mode. If the controller channel operates in the power-saving mode prior to the VID on-the-Fly transition, it will change to high performance mode and implement CCM operation when the controller implement VID up, and then remain in high performance mode; if the controller implement VID down in power-saving mode, it will decay down and keep in power-saving mode. The voltage at the PGOOD pin will keep high during the VID on-the-Fly transition. The RT3662EB send a VOTF complete only at the end of VID up transition. In the event of receiving a VID off code, the RT3662EB steps the reference voltage of required controller channel down to zero, hence making the required output voltage decrease to zero, and the voltage at the PGOOD pin will remain high since the VID code is valid.

**Power State Transition**

The RT3662EB supports power state transition function in VDDC VR for the PSI[x]\_L command from AMD processor. The PSI[x]\_L bit in the SVI2 protocol controls the operating mode of the RT3662EB controller channels. The default operation mode of VDDC VR is full-phase CCM.

When the VDDC VR is in N phase configuration and receives PSI0\_L = 0 and PSI1\_L = 0 or 1, it will entry 1-phase diode emulation mode. When the VDDC VR receives PSI0\_L = 1 and PSI1\_L = 0, it remains 1-phase diode emulation mode. In reverse, the VDDC VR goes back to N phase operation in CCM upon receiving PSI0\_L = 1 and PSI1\_L = 1, see Table 7.

Table 7. VDDC VR Power State

Full Phase Number	PSI0_L : PSI1_L	Mode

	10	1 phase DEM
	01	
	00	
1	11	1 phase CCM
	10	1 phase DEM
	01	
	00	

**Differential Remote Sense Setting**

The VDDC controller has differential remote-sense inputs to eliminate the effects of voltage drops along the PC board traces, processor internal power routes and socket contacts. The processor contains on-die sense pins, including of VDDC\_SENSE, and VSS\_SENSE. For VDDC controller, connect FB to VDDC\_SENSE with a resistor to build the negative input path of the error amplifier, and connect VSS\_SENSE to RGND as shown in Figure 4. The precision reference voltages refer to RGND for accurate remote sensing.

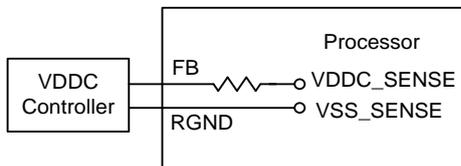

Figure 4. Differential Remote Sense Connection

**SET1 Pin Setting**

The RT3662EB provides the SET1 pin for platform users to set the VDDC controller current gain ratio (AI\_VDDC), QR threshold (QR\_TH). Platform designers should use resistive voltage divider on the pin, refer to Figure 5. The voltage (VREF) at VREF\_PINSET pin will be pulled up to 3.2V for SET1 pin setting after power ready (POR), and then the voltage will change and fix to 0.8V with a delay time for normal operation.

The divided voltage at the SET1 pin as below :

$$V_{SET1\_DIV} = 3.2 \times \frac{R_D}{R_U + R_D} \tag{1}$$

The ADC monitors and decodes the voltage at this pin only once after power up. After ADC decoding (only once), a 80μA current (when VCC = 5V) will be generated at the SET1 pin for pin setting. That is the voltage at SET1 pin described as below:

$$V_{SET1\_IR} = 80\mu \times \frac{R_U \times R_D}{R_U + R_D} \tag{2}$$

From equation (1) and (2) and Table 2 and 3, platform users can set the above described pin setting functions.

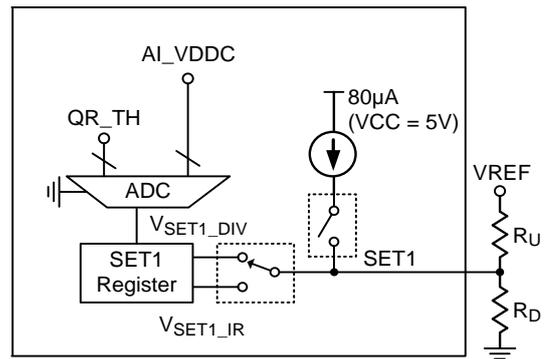

Figure 5. SET1 Pin Setting

**TSEN Pin Setting**

The RT3662EB provides the TSEN pin for platform users to set the pin setting functions, including the VDDC controller switching frequency (Fsw), Initial offset and per-phase over current protection (PHOCP). Platform designers should use resistive voltage divider on the pin, refer to Figure 6. The voltage (VREF) at VREF\_PINSET pin will be pulled up to 3.2V for TSEN pin setting after power ready (POR), and then the voltage will change and fix to 0.8V with a delay time for normal operation.

The divided voltage at the TSEN pin described as below :

$$V_{TSEN\_DIV} = 3.2 \times \frac{R_{p2}}{R_{p1} + R_{p2}} \tag{3}$$

The ADC monitors and decodes the voltage at this pin only once after power up. After ADC decoding (only once), a 80μA current (when VCC = 5V) will be generated at the TSEN pin for thermal indicator and protection functions.

From equation (3) and Table 4, platform users can set the above described pin setting functions.

**Thermal Indicator**

Refer to Figure 6, the RT3662EB provides the thermal indicator. The VRHOT\_L pin is an open-drain output which is used for VR thermal indicator. When the sensed voltage at TSEN pin is less than 2.2V, the VRHOT\_L signal will be pulled low to notify GPU that the temperature is over the VRHOT temperature threshold.

After TSEN pin setting, a 80µA current (when VCC = 5V) will be generated at the TSEN pin for thermal indicator function. And the voltage at TSEN pin as below :

$$V_{TSEN} = 80\mu A \cdot \left[ \left( \frac{R_1 \cdot R_{NTC}}{R_1 + R_{NTC}} \right) + \left( \frac{R_{p1} \cdot R_{p2}}{R_{p1} + R_{p2}} \right) \right] + VREF \cdot \left( \frac{R_{p2}}{R_{p1} + R_{p2}} \right) \quad (4)$$

Due to the VREF reference voltage cause the thermal compensation become complex. In this way, the sensed voltage related VREF will be eliminated in ADC block. The actual sensed voltage at TSEN pin described as below :

$$V_{TSEN\_ADC} = 80\mu A \cdot \left[ \left( \frac{R_1 \cdot R_{NTC}}{R_1 + R_{NTC}} \right) + \left( \frac{R_{p1} \cdot R_{p2}}{R_{p1} + R_{p2}} \right) \right] \quad (5)$$

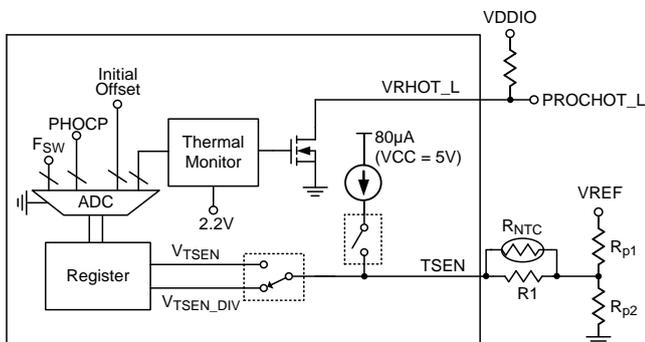

Figure 6. TSEN Circuit

**VDDC Controller**

**Active Phase Determination**

The number of active phases is determined by the internal circuitry that monitors the ISEN2N voltage during start-up. Normally, the VDDC controller operates as a 2-phase PWM controller. Pulling ISEN2N to VCC programs a 1-phase operation. At EN rising edge, VDDC controller detects whether the voltage of ISEN2N is higher than “VCC – 0.5V” to decide how many phases should be active and the active phase number is determined and latched. The unused ISEN2P pin is

recommended to be connected to VCC.

**Loop Control**

The VDDC controller adopts Richtek's proprietary G-NAVP™ topology. The G-NAVP™ is based on the finite gain peak current mode with CCRCOT (Constant Current Ripple Constant On-Time) topology. The output voltage, VVDDC will decrease with increasing output load current. The control loop consists of PWM modulators with power stages, current sense amplifiers and an error amplifier as shown in Figure 7.

Similar to the peak current mode control with finite compensator gain, the HS\_FET on-time is determined by CCRCOT on-time generator. When load current increases (Vcs increases), the steady state COMP voltage also increases and induces VVDDC\_SENSE to decrease, thus achieving AVP. A near-DC offset canceling is added to the output of EA to eliminate the inherent output offset of finite gain peak current mode controller.

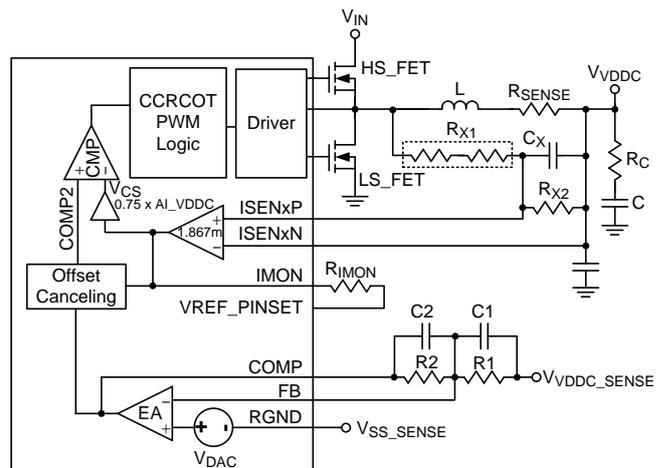

Figure 7. VDDC Controller : Simplified Schematic with Voltage Loop and Current Loop

**Current Signal Sensing**

Refer to Figure 7, for different RSENSE resistor, the current sense method can classify as two types. The method1 only use Rx1 for lower RSENSE application, and the method2 use Rx1 and Rx2 to divide the current signal for higher RSENSE application. Richtek also provide Excel based design tool to let user choose the appropriate components quickly.

The current sense topology of the VDDC controller is continuous inductor current sensing. Therefore, the

controller has less noise sensitive. Low offset amplifiers are used for current balance, loop control and over current detection. The ISENxP and ISENxN pins denote the positive and negative input of the current sense amplifier.

In order to optimize transient performance, the recommended  $R_{eq}$  and  $C_X$  will be set according to the equations as below,  $\tau$  recommended set to 1.1.

$$R_{eq} \times C_X = \tau \times \frac{L}{R_{SENSE}} \quad (6)$$

Method1 :  $R_{eq} = R_{X1}$

$$\text{Method2 : } R_{eq} = \frac{R_{X1} \times R_{X2}}{R_{X1} + R_{X2}}$$

Considering the inductance tolerance, the resistor  $R_{eq}$  has to be tuned on board by examining the transient voltage. If the output voltage transient has an initial dip below the minimum load-line requirement and the response time is too fast causing a ring back, the value of resistance should be increased. Vice versa, with a high resistance, the output voltage transient has only a small initial dip with a slow response time.  $R_X$  is highly recommended as two 0603 size resistors in series to enhance the lout reporting accuracy.  $C_X$  is suggested X7R type for the application.

**Droop Setting**

It is very easy to achieve Active Voltage Positioning (AVP) by properly setting the error amplifier gain due to the native droop characteristics as shown in Figure 8. This target is to have

$$V_{VDDC} = V_{DAC} - I_{LOAD} \times R_{DROOP} \quad (7)$$

Then solving the switching condition  $V_{COMP2} = V_{CS}$  in Figure 7 yields the desired error amplifier gain as

$$A_V = \frac{R_2}{R_1} = \frac{G_I}{R_{DROOP}} \quad (8)$$

Method1 :

$$G_I = R_{SENSE} \times 1.867m \times R_{IMON} \times 0.75 \times AI\_VDDC \quad (9)$$

Method2 :

$$G_I = R_{SENSE} \times \frac{R_{X2}}{R_{X1} + R_{X2}} \times 1.867m \times R_{IMON} \times 0.75 \times AI\_VDDC \quad (10)$$

Where  $G_I$  is the current sense amplifier gain.  $R_{SENSE}$  is

the current sense resistor. If no external sense resistor present, it is the equivalent resistance of the inductor.  $R_{IMON}$  is the  $IMON$  equivalent resistance. For the PHOCP accuracy, the  $R_{IMON}$  resistor need to set in  $8k\Omega$  to  $70k\Omega$ .  $AI\_VDDC$  is the  $VDDC$  controller current gain ratio set by SET1 pin setting.  $R_{DROOP}$  is the equivalent load-line resistance as well as the desired static output impedance.

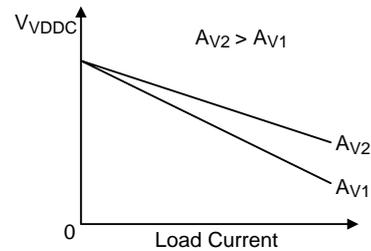

Figure 8. VDDC Controller : Error Amplifier gain ( $A_V$ ) Influence on  $V_{VDDC}$  Accuracy

**Loop Compensation**

Optimized compensation of the  $VDDC$  controller allows for best possible load step response of the regulator's output. A type-I compensator with one pole and one zero is adequate for proper compensation. Figure 9 shows the compensation circuit. Previous design procedure shows how to select the resistive feedback components for the error amplifier gain. Next,  $C_1$  and  $C_2$  must be calculated for compensation. The target is to achieve constant resistive output impedance over the widest possible frequency range.

The pole frequency of the compensator must be set to compensate the output capacitor ESR zero :

$$f_p = \frac{1}{2\pi \times C \times R_C} \quad (11)$$

Where  $C$  is the capacitance of output capacitor, and  $R_C$  is the ESR of output capacitor.  $C_2$  can be calculated as follows :

$$C_2 = \frac{C \times R_C}{R_2} \quad (12)$$

The zero of compensator has to be placed at half of the switching frequency to filter the switching related noise. Such that,

$$C_1 = \frac{1}{R_1 \times \pi \times f_{SW}} \quad (13)$$

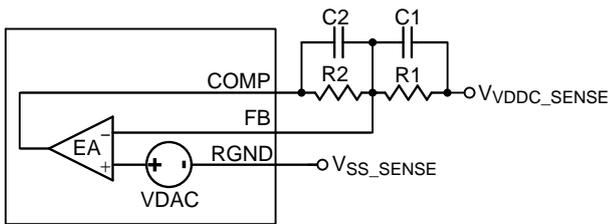

Figure 9. VDDC Controller : Compensation Circuit

**Current Balance**

The VDDC controller implements internal current balance mechanism in the current loop. The VDDC controller senses and compares per-phase current signal with average current. If the sensed current of any particular phase is larger than average current, the on-time of this phase will be adjusted to be shorter.

**Initial and Dynamic Offset**

The VDDC controller features initial and dynamic offset function. The VDDC rail initial offset function can be implemented through the TSEN pin setting. And the dynamic offset can be implemented by SVI2 interface, it controlled by GPU. Consider the offset factor, the VDDC output voltage described as below :

$$V_{VDDC} = V_{DAC} - I_{LOAD} \times R_{DROOP} + V_{INI\_OFS} + V_{DYN\_OFS} \quad (14)$$

$V_{INI\_OFS}$  is the initial offset voltage set by pin setting function, and the dynamic offset voltage,  $V_{DYN\_OFS}$ , controlled by GPU, and it can be set through the SVI2 interface.

**Dynamic VID Enhancement**

During a dynamic VID event, the charging (dynamic VID up) or discharging (dynamic VID down) current causes unwanted load-line effect which degrades the settling time performance. The RT3662EB will hold the inductor current to hold the load-line during a dynamic VID event. The VDDC controller will always enter full-phase configuration when it receives dynamic VID up command; If VDDC controller receives dynamic VID down command, it will hold the operating state.

When the VID CCM down on light loading condition, the negative inductor current will be produced, and it will cause the audio noise and phase ring effect. For improving the problems, the controller set the dynamic VID down slew rate to 0.625mV/ $\mu$ s, the action will reduce the negative current and phase ring effect.

**Ramp Compensation**

G-NAVP™ topology is one type of ripple based control that has fast transient response. However, ripple based control usually don't have good noise immunity. The RT3662EB provides a ramp compensation to increase noise immunity and reduce jitter at the switching node, refer to Figure 10 shows the ramp compensation. When the VDDC controller takes phase shedding operation and enters diode emulation mode, the internal ramp of VDDC controller will be modified for the reason of stability.

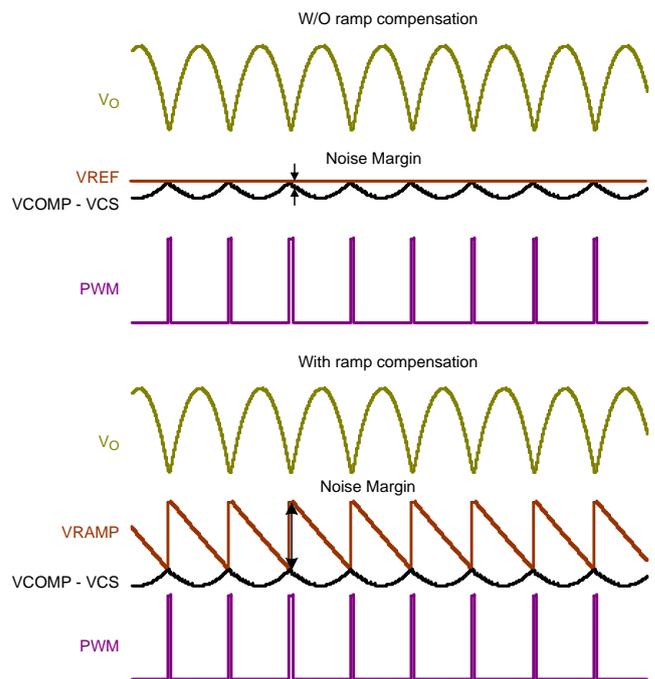

Figure 10. Ramp Compensation

**Current Monitoring and Reporting**

The VDDC controller provides current monitoring function via inductor current sensing. In the G-NAVP™ technology, the output voltage is dependent on output current, and the current monitoring function is achieved by this characteristic of output voltage. The equivalent output current will be sensed from inductor current sensing and mirrored to the IMON pin. The resistor connected to the IMON pin determines voltage of the IMON output.

For Method1 current sensing :

$$V_{IMON} = I_{L,SUM} \times DCR_L \times 1.867m \times R_{IMON} + 0.8 \quad (15)$$

Where  $I_{L,SUM}$  is the VDDC output current,  $DCR_L$  is the current sense resistance,  $R_{IMON}$  is the IMON pin

equivalent setting resistor, and the current sense gain equal to 1.867m.

The ADC circuit of the VDDC controller monitors the voltage variation at the IMON pin, and this voltage is decoded into digital format and stored into output current register.

$$DIMON = \frac{V_{IMON} - 0.8}{0.8} \times 255 \quad (\text{Bits}) \quad (16)$$

### Quick Response

When the transient load step-up becomes quite large, it is difficult for loop response to meet the energy transfer. Hence, the output voltage generate undershoot to fail specification. The RT3662EB has Quick Response (QR) mechanism which is able to improve this issue. It adopts a nonlinear control mechanism which can disable interleaving function and simultaneously turn on all UGATE one pulse at instantaneous step-up transient load to restrain the output voltage drooping. The output voltage signal behavior needs to be detected so that QR mechanism can be triggered. Refer to Figure 11, the output voltage signal is via a remote sense line to connect at the VSEN pin. The QR threshold can be set by SET1 pin setting for VDDC controller refers to Table 3.

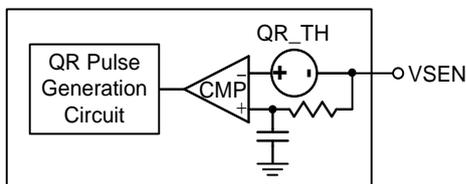

Figure 11. VDDC Controller : Quick Response Triggering Circuit

### Over-Current Protection

The RT3662EB provides the over current protection function. The OCP\_SPIKE threshold will be set by the current monitor resistor R<sub>IMON</sub> as below :

For Method1 current sensing :

$$OCP\_SPIKE = \frac{1.6 - 0.8}{DCR_L \times 1.867m \times R_{IMON}} \quad (17)$$

For prevent the OCP false trigger, the trigger delay is requirement, refer to Electrical Characteristics. When output current is still higher than the OCP\_SPIKE after the trigger delay time, the OCP will be latched, and then the VDDC controller will turn off both high-side and

low-side MOSFETs of all channels.

### Per-Phase Over Current Protection

The VDDC controller provides per-phase over current protection (PHOCP) function in each phase. If the VDDC controller force 1 phase operation by pulling ISEN2N pin to 5V, it only detected at soft-start duration when VR power on. The VDDC PHOCP threshold is set by TSEN pin setting described as below :

$$PHOCP\_TH = OCP\_SPIKE \times \frac{N}{M} \quad (18)$$

N is the VDDC PHOCP setting ratio, M is the operation phase number.

If the PHOCP is triggered, the controller will turn off all high-side and low-side MOSFETs to protect GPU.

### Over-Voltage Protection (OVP)

The OVP circuit of the VDDC controller monitors the output voltage via the VSEN pin after POR. When the VSEN voltage exceeds the OVP threshold 1.85V, OVP is triggered and latched. The VDDC controller will try to turn on low-side MOSFET and turn off high-side MOSFET of all active phases to protect the GPU. A 1μs delay is used in OVP detection circuit to prevent false trigger.

### Under-Voltage Protection (UVP)

The VDDC controller implements UVP of VSEN pin. If VSEN voltage is less than the internal reference by 500mV, the VDDC controller will trigger UVP latch. The UVP latch will turn off both high-side and low-side MOSFETs. A 3μs delay is used in UVP detection circuit to prevent false trigger.

### Under-Voltage Lock Out (UVLO)

During normal operation, if the voltage at the VCC pin drops below IC POR threshold, the VDDC controller will trigger UVLO. The UVLO protection forces all high-side and low-side MOSFETs off by shutting down internal PWM logic drivers. A 3μs delay is used in UVLO detection circuit to prevent false trigger.

### Thermal Considerations

The junction temperature should never exceed the absolute maximum junction temperature T<sub>J(MAX)</sub>, listed under Absolute Maximum Ratings, to avoid permanent

damage to the device. The maximum allowable power dissipation depends on the thermal resistance of the IC package, the PCB layout, the rate of surrounding airflow, and the difference between the junction and ambient temperatures. The maximum power dissipation can be calculated using the following formula :

$$P_{D(MAX)} = (T_{J(MAX)} - T_A) / \theta_{JA}$$

where  $T_{J(MAX)}$  is the maximum junction temperature,  $T_A$  is the ambient temperature, and  $\theta_{JA}$  is the junction-to-ambient thermal resistance.

For continuous operation, the maximum operating junction temperature indicated under Recommended Operating Conditions is 125°C. The junction-to-ambient thermal resistance,  $\theta_{JA}$ , is highly package dependent. For a WQFN-32L 4x4 package, the thermal resistance,  $\theta_{JA}$ , is 27.8°C/W on a standard JEDEC 51-7 high effective-thermal-conductivity four-layer test board. The maximum power dissipation at  $T_A = 25^\circ\text{C}$  can be calculated as below :

$$P_{D(MAX)} = (125^\circ\text{C} - 25^\circ\text{C}) / (27.8^\circ\text{C/W}) = 3.59\text{W for a WQFN-32L 4x4 package.}$$

The maximum power dissipation depends on the

operating ambient temperature for the fixed  $T_{J(MAX)}$  and the thermal resistance,  $\theta_{JA}$ . The derating curves in Figure 12 allows the designer to see the effect of rising ambient temperature on the maximum power dissipation.
